An immortalized human keratinocyte cell line has been described which is derived from a non-transformed primary keratinocyte cell line. This cell line was termed the HEP line. We now report the derivation of a murine keratinocyte cell line containing the HEP phenotype which will allow for further analysis of the differentiation properties of keratinocytes. Unlike the original HEP line, the derived cell line will spontaneously form colonies when plated at clonal density. Both cell lines will undergo terminal differentiation and cyclic AMP-dependent morphological changes when exposed to physiologic calcium concentrations. The HEP line expresses a very low level of class I MHC genes, and will form a thymidine-independent plasmacytoma when transplanted into athymic mice. The HEP line will be an extremely useful model for the analysis of growth factors in the epithelium of skin. As well, it may be useful for the isolation of cytostatic agents from wound fluids or exfoliative fluids.About this mod This mod allows you to use VWP effects under both the Lua and the C
